

PC-Kote[™] 100 System

APPLICATION INSTRUCTIONS

SUPER-KRETE PRODUCTS REQUIRED:

- SK-E100 Pigmented
- SK-P100 Pigmented
- SK-P100 VOC Pigmented
- SK-P501 Pigmented

GENERAL

PC-Kote 100 is a thin film protective coating, consisting of two component epoxy primer and a two component chemical resistant polyurethane top coat. PC-Kote 100 offers high gloss easy to clean surface, with excellent chemical and abrasion resistance. PC-Kote 100 suitable for use in applications such as light manufacturing, warehouses, retail and garage floors.

MOISTURE VAPOR EMISSIONS TESTING

All interior concrete floors are subject to possible moisture vapor emission and/or excessive alkalinity that could ultimately cause coating failure. Prior to application, calcium chloride moisture testing should be conducted according to ASTM 1869-04.

SURFACE PREPARATION

Surface preparation is vital to the long term success of the installation. All surfaces to be coated must be clean, sound and free of mastics or other contaminants which may interfere with bonding. The concrete must be shot-blasted or diamond ground to achieve a CSP 1-3. Properly prepared concrete must have a texture similar to 80-120 grit sandpaper.

Small depressions, cracks and holes should be filled with *SK-E300 Flex Paste* or *SK-E400* thickened with fumed silica. Large holes should be filled with an epoxy mortar consisting of 4-5 parts aggregate (30 mesh silica or graded trowel sand) to 1 part *SK-E400*. This mortar must be placed directly over a primer coat of *SK-E400* while the primer is still wet.

APPLICATION OF PRIMER COAT

Mix **SK-E100** pigmented 4 parts A to 1 B, mix the two components using a low speed drill for 1 minute. Then add 20-30% water and mix for an additional 2 minutes using a low speed drill. It is important to mix no more material then can be applied in 45 minutes.

Once the material is completely mixed pour a usable amount on to the floor. Use a cut in brush to coat the edges and control joints, then using a flat squeegee or roller spread the material at a rate of 200-250 square feet per gallon. Once the material is spread evenly it must be back rolled to ensure even coverage.

If a non-skid texture is desired, you may broadcast a 30-40 mesh particle into the wet coating and then back rolled to ensure an even distribution. Allow the primer to cure for 8-12 hours prior to proceeding with the top coat.

APPLICATION OF POLYURETHANE TOPCOAT

Once the **SK-E100** is cured you can apply the polyurethane top coat. Prior to the installation of the topcoat it is recommended that you make a visual inspection of the primer, looking for any debris that has been trapped in the primer. A razor blade scrapper or sand paper should be used to remove any imperfections. Make sure to sweep or vacuum the surface prior to proceeding with the top coating process.

Mix the specified polyurethane at the ratio on the data sheet for 2 minutes, then immediately pour a usable amount onto the floor and spread it using a flat squeegee or roller. As soon as the material is spread back role using a 3/8" nap roller to insure an even coverage. It is very important keep a wet edge when installing the pigmented polyurethane top coat, no more than 5 minutes should elapse between sections. Failure to keep a wet edge could result in a visible tie in line. For exterior desert applications a UV package must be incorporated.

The application rate of this coat should be 250-325 square feet per gallon. Over application of the polyurethane could lead to film defects such as bubbles, blisters and overall softness of the top coat.
